1. Experimental

1.1. Method used for the measurement of jute fabrics’ capillarity

The jute fabrics’ capillarity measurements were performed on an appliance which is presented in Fig. S1. Namely, the jute fabrics (25 cm x 2 cm in warp direction) were placed in a vertical position. Their one end was fixed with a clip on the horizontal bar, while the other end
was pre-loaded with a tag of 2 g and immersed approximately 2 cm in depth into 0.1% aqueous solution of eosin (red-colored) which level was above tag and overlapped with 0 cm at rulers printed along with the vertical plate. When the samples were immersed in eosin, the GoPro Hero 4 camera started to take pictures at time intervals of 1 min in the first 10 min and every 5 min up to attaining capillary rise equilibrium.

![Appliance used for capillary rise measurements](image)

Fig. S1 Appliance used for capillary rise measurements

Based on the experimental data obtained by capillarity measurements and methodology described by Pejić et al. (2020), the three wettability parameters were determined by using Eqs. (1-4).

\[ h^2 = D \cdot t \] \hspace{1cm} (1)

where: \( D \) (mm\(^2\)/s) is a capillary diffusion coefficient;

\[ H = C \cdot t \] \hspace{1cm} (2)

where: \( C \) (mm/s) is a coefficient related to the mean hydrodynamic pores radius and the liquid nature, while \( H \) values were determined as:
\[ H = h_{eq} \cdot \ln \frac{h_{eq}}{h_{eq}^2 + h} \quad (3) \]

Coefficient \( R \), which confirms the validity of assumption \( \theta = \theta_{eq} \) is given by:

\[ R = \frac{\cos \theta}{\cos \theta_{eq}} = \frac{D}{2 \cdot C \cdot h_{eq}} \quad (4) \]

where: \( \theta \) and \( \theta_{eq} \) (°) are the dynamic and static contact angles of the liquid on the solid.

2. Results

2.1. Jute fabrics’ structural characteristics

Table S1 Jute fabrics’ structural characteristics (The results were previously published by Ivanovska et al. 2019, 2020)

2.4. Content of carboxyl and aldehyde groups

The carboxyl group content was determined using the calcium-acetate method (Knežević et al., 2020). The cellulose carboxyl groups react with calcium acetate (weak acid salt), forming
a salt of the cellulose and releasing an equivalent amount of the weaker acid. The cellulose should be obtained in the acidic form by replacement of its cations with hydrogen ions by the treatment of jute sample (0.5 g) with 100 mL of 0.01 M HCl solution for 1 h followed by washing with distilled water. In the next step, 50 ml of distilled water and 30 ml of 0.25 M calcium acetate were added and the mixture was stirred for 2 h. Thereafter, 30 ml portions of the liquid were titrated with 0.01 M NaOH solution, using phenolphthalein as an indicator. The quantity of carboxyl groups \( (Q(COOH), \text{mmol/g}) \) was calculated as follows, Eq. 5:

\[
Q(COOH) = \frac{80 \cdot 0.01 \cdot V(\text{NaOH})}{30 \cdot m}
\]  

(5)

where 0.01 is NaOH concentration, mol/l, \( V(\text{NaOH}) \) is the volume of NaOH solution used for titration, ml, \( m \) is the weight of absolutely dry jute fabric, g.

The content of aldehyde groups was determined according to the method described by Saito and Isogai (2004). In order to selectively oxidize the sample’s aldehyde groups to carboxyl groups, 1 g of a sample was added to a mixture containing 0.905 g NaClO₂, 10 ml of 5 M CH₃COOH solution, and 50 ml of distilled water. Oxidation was carried out by mixture stirring at room temperature for 48 h, and thereafter, the sample was thoroughly washed with distilled water and acetone. Further, the previously described calcium acetate method for determining the content of carboxyl groups was applied. The content of aldehyde groups was calculated by subtracting the content of carboxyl groups determined in the starting sample from that of chlorite oxidized one.
